General Description

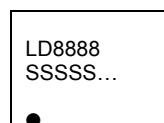

The 4275K is a monolithic integrated low-drop voltage regulator in a 5 pin TO- package. An input voltage up to 45V is regulated to $V_Q = 5.0V$. The IC is able to drive loads up to 450mA and is short-circuit proof. At over temperature the 4275K is disabled by the incorporated temperature protection. A reset signal is generated for an output voltage V_Q of typ.4.65V. The delay time can be programmed by the external delay capacitor.

Absolute Maximum Ratings

Parameter	Maximum	Unit
Voltage regulator input voltage	45	V
Voltage regulator input current	Internally limited	
Output voltage	16	V

Reset output voltage	25	V
Reset output current	5	mA
Reset delay voltage	7	V
Reset delay current	2	mA

The values beyond the boundaries of absolute maximum rating may cause the damage to the device. Functional operation in this context is not implied. Continuous use of the device at the absolute rating level might influence device reliability. All voltages have their reference to device ground.

Note: Maximum ratings are absolute ratings; exceeding any one of these values may cause irreversible damage to the integrated circuit.

Pin Description

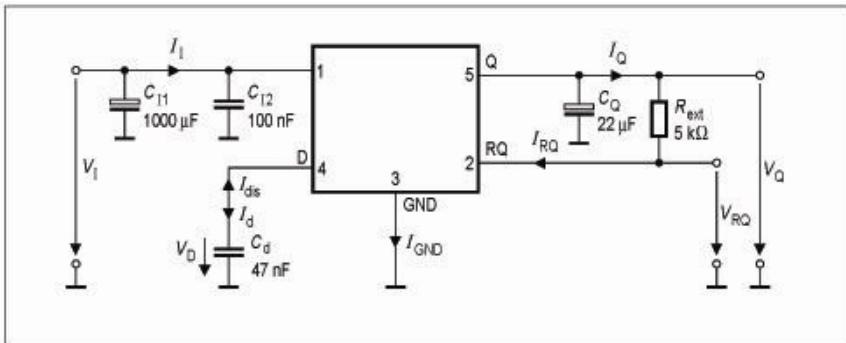

Pin No.	Name	Description
1	I	Input, block to ground directly at the IC with a ceramic capacitor
2	RQ	Reset Output, open collector output
3	GND	Ground, pin 3 internally connected to heat sink
4	D	Reset Delay, connected capacitor to GND for setting delay time
5	Q	Output, Block to ground with a $\geq 22\mu F$ capacitor, ESR < 5Ω at 10kHz

Block Diagram**Circuit Description**

The control amplifier compares a reference voltage to a voltage that is proportional to the output voltage and drives the base of the series transistor via a buffer. Saturation control as a function of the load current prevents any oversaturation of the power element. The IC also incorporates a number of internal circuits for protection against:

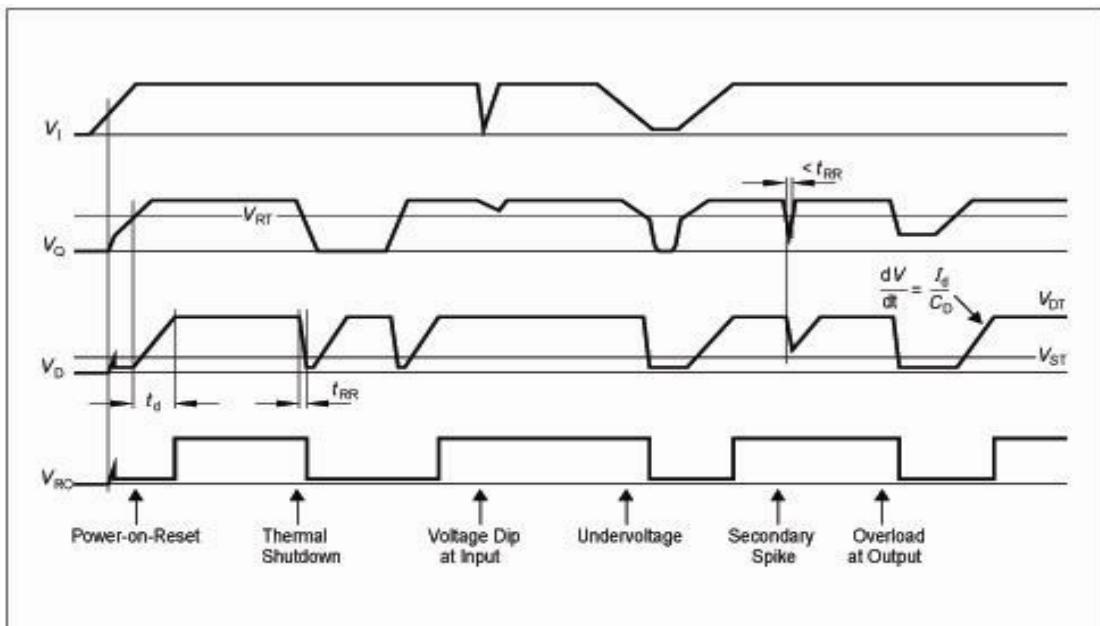

- Overload
- Over- temperature
- Reverse polarity

Typical Application Circuit

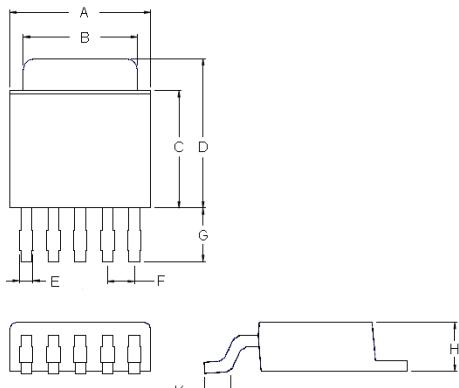

Information on External Components

The input capacitor C_1 is necessary for compensating line influences. The output capacitor C_Q is necessary for the stability of the regulation circuit. Stability is guaranteed at values $C_Q \geq 22\mu\text{F}$ and an ESR of $\leq 5\Omega$ within the operating temperature range.
